

how the retrieval works

(a)

what the satellite records

one value per band, seen from above

(b)

inversion against a simulated library

a regressor is trained on the library

the prescribed parameter ranges are the prior, and they are tuned for crops

what limits it

(c)

different canopies, one spectrum

so the retrieval needs a prior to choose

(d)

and the response saturates

differences stop reaching the sensor

wall-to-wall and repeated, but two-dimensional: the depth of the canopy is what the signal cannot reach
