

airborne LiDAR

Sentinel-2

how one
acquisition
works

energy source	its own laser pulse	sunlight the canopy reflects
what is measured	the time each return takes to come back	radiance in each spectral band
one acquisition returns	many ranged returns per pulse, in three dimensions	one value per band over a 10 or 20 m pixel
what limits it	the flight plan, the pulse density, the cost	cloud cover, and the sun and view angles

one instrument is active and resolves height; the other is passive and resolves colour
